Chapter 1

Introduction

IMITATOR is a free, open source software tool to perform automated parameter synthesis for concurrent timed systems [And+12]. IMITATOR takes as input a network of IMITATOR parametric timed automata (NIPTA): NIPTA are an extension of parametric timed automata [AHV93], a well-known formalism to specify and verify models of systems where timing constants can be replaced with parameters, i.e., unknown constants.

IMITATOR addresses several variants of the following problem: “given a concurrent timed system, what are the values of the timing constants that guarantee that the model of the system satisfies some property?” Specifically, IMITATOR implements parametric safety analysis [AHV93; JLR15], the inverse method [And+09; AM15], the behavioral cartography [AF10], and parametric reachability preservation [And+15]. Some algorithms can also run distributed on a cluster. Numerous analysis options are available.

IMITATOR is a command-line only tool, but that can output results in graphical form.

IMITATOR was able to verify numerous case studies from the literature and from the industry, such as communication protocols, hardware asynchronous circuits, schedulability problems and various other systems such as coffee machines (probably the most critical systems from a researcher point of view). Numerous benchmarks are available at IMITATOR Web page [IMI-Web].

In this document, we present the input syntax, we formally define the input model of IMITATOR, and we explain how to perform various analyses using the numerous options.

Keywords: formal verification, model checking, software verification, parameter synthesis
Chapter 2

A brief introduction to the syntax

We first briefly introduce the syntax using a simple example for readers familiar with parametric timed automata, and not interested in subtle details (such as the synchronization model). A formal (and nearly exhaustive) definition of IMITATOR parametric timed automata (NIPTA) can be found in Chapter 3. The complete syntax is given in Chapter 9.

**Generalities** IMITATOR performs parametric verification of models specified using networks of IMITATOR parametric timed automata (hereafter NIPTA). An IMITATOR parametric timed automaton (hereafter IPTA) is a variant of parametric automata (as introduced in [AHV93]). IPTA and NIPTA are formalized in Section 3.1.

The input syntax of IMITATOR is originally based on the syntax of HyTech [HHW95], with several improvements. Actually, all standard HyTech files describing only PTA (and not more general systems like linear hybrid automata [Alu+93]) can be analyzed directly by IMITATOR (sometimes with very minor changes).

Comments are OCaml-like comments starting with (\*) and ending with (\*). As in OCaml, comments can be nested.

**The Fischer mutual exclusion protocol** We use as a motivating example one timed version of the Fischer mutual exclusion protocol, coming from the PAT model checker [Sun+09]. This version of the protocol is neither the most complete, nor the most simple; we just use it here to introduce various aspects of the IMITATOR input syntax.

Fischer mutual exclusion protocol is a protocol that guarantees the mutual exclusion of several processes (here two) that want to access a shared resource (called the critical section).

**Input syntax** We give below this model using the IMITATOR syntax. This model is given in graphical form in Fig. 2.1.\(^1\)

\[
\begin{aligned}
&\text{IMITATOR MODEL} \\
&\text{Fischer’s mutual exclusion protocol}
\end{aligned}
\]

\(^1\)This \LaTeX\ representation, that makes use of the \LaTeX\ TikZ library, was automatically output by IMITATOR, using option `-PTA2TikZ`, followed by some manual positioning optimization.
* Description : Fischer’s mutual exclusion protocol with 2 processes
* Correctness : Not 2 processes together in the critical section (location ob_violation unreachable)
* Source : PAT library of benchmarks
* Author : Etienne Andre
* Input by : Etienne Andre
* Created : 2012/10/08
* Last modified : 2015/07/20
* IMITATOR version : 2.7

**Header** Let us comment this case model by starting with the header. First, text in comments gives generalities about the model (author, date, description, etc.). The form is not normalized, but it could be in the future, so it is strongly advised to follow this form.\(^2\)

**Variable declarations** The variable declarations starts with keyword `var`. This model contains two clocks: \(x_1\) is process 1's clock, and \(x_2\) is process 2's clock.

This model contains two parameters: \(\delta\) is the parametric duration specifying how long a process is idle at most, whereas \(\gamma\) is the parametric duration specifying the minimum duration between the time a process checks for the availability of the critical section and the time the same process indeed enters the critical section (if it is still available).

Two discrete variables (i.e., global, rational-valued variables, see Section 3.2) are used: \(\text{turn}\) checks which process is attempting to enter the critical section; \(\text{counter}\) records how many processes are in the critical section (this variable will not be used for the verification, but was used in the original PAT model, and we choose to keep it).

\(^2\)An empty model template with all these comments ready to be filled out (containing also a sample IPTA and its initial definitions) is available at: https://github.com/etienneandre/imitator/blob/master/benchmarks/model.imi.
Finally, a global constant `IDLE` is set to -1 (just as in the original PAT model), and encodes that no process is attempting to enter the critical section.

**Automata** This model contains three IPTA: the first and second ones (`proc1` and `proc2`) model the first and second process, respectively. The third one (`observer`) is an observer, i.e., an IPTA that checks the system behavior without modifying it.

**The first process** Let us first describe the IPTA `proc1` (a graphical representation is given in Fig. 2.1a). This IPTA uses six actions, given in the `synclabs` declaration.

`proc1` is initially in location `idle1`, with no invariant (depicted by `invariant True`). At any time, when the discrete variable `turn` is equal to `IDLE`, then this IPTA may synchronize on action `try_1`, reset its clock `x1`, and enter location `active1`.

The invariant of this location is `x1 <= delta`, i.e., `proc1` can only remain in `active1` as long as the value of `x1` does not exceed `delta`. At any time, this IPTA may synchronize on action `update_1`, reset its clock `x1` and set the global variable `turn` to 1, and enter location `check1`.

In location `check1`, the process wait at least `gamma` time units (modeled by the inequality `x1 >= gamma`, in all outgoing transitions). If `turn` is still equal to 1 (that is, no other process attempted in the meanwhile to enter the critical section), then process 1 is indeed ready to enter the critical section, by synchronizing `access_1` and resetting `x1`. If `turn` is different from 1 (that is, another process attempted in the meanwhile to enter the critical section, and it is not safe for process 1 to enter), then process 1 returns to its idle location, by synchronizing `no_access_1` and resetting `x1`. Note that we have to use two transitions checking that either `turn < 1` or `turn > 1` to compensate that the “different from” operator ("\(\neq\)"") is not (yet) supported by IMITATOR.

In location `access1`, process 1 can remain any time, and eventually enters the critical section by synchronizing `enter_1` and incrementing the global variable `counter` by 1.

In location `CS1`, process 1 can remain any time, and eventually leaves it, by decrementing the global variable `counter` by 1, and setting the global variable `turn` to its initial value `IDLE`.

**The second process** Process 2 is identical to process 1, except that `x1` is replaced with `x2`, and that the value of `turn` becomes 2.

**The observer** The observer is in charge to check that no more than one process is in critical section at the same time.\(^3\) This observer will detect that this situation happens if an action `enter_1` is followed by an action `enter_2` without an action `exit_1` in between (or symmetrically if an action `enter_2` is followed by an action `enter_1` without an action `exit_2` in between). Note that the observer simply observes the system state, and synchronizes on the actions used by `proc1` and `proc2`; it does not use any clock nor variable.

---

\(^3\)This observer is not really necessary to check the correctness of this protocol; instead of adding this observer and checking `unreachable loc[observer] = obs_violation`, one could just check either `counter > 1` or `loc[proc1] = CS1 & loc[proc2] = CS2`. However, this example comes from an earlier version of IMITATOR (that did not support checking global variables or more that one location in the unreachable property — which has been fixed since version 2.7); furthermore, introducing an observer is also useful, as it is often used for the verification of more complex properties (see, e.g., [ABL98; Ace+98]).
Figure 2.1: Fischer mutual exclusion protocol (graphical NIPTA)
A graphical representation of the IPTA observer is given in Fig. 2.1b.

**Initial definitions**  The initial state is defined the part of the file following `init :=`. This part must contain the initial location of each IPTA. For example, `loc[proc1] = idle1` states that `proc1` is initially in location `idle1`.

The initial definition may (only may, see Section 3.3) give an initial value to the clocks, for example requiring them to be equal to some constant (typically 0). Here, clocks are only bound to be greater or equal to 0.

The initial definition should assign a constant value to each discrete variable: here `turn` is initially equal to `IDLE`, and `counter` is initially equal to 0.

Finally, parameters are bound to be positive or null (this is not assumed by default by IMITATOR, so users are strongly advised to add this constraint).

Note that the initial definition can introduce more complex constraints on clocks, parameters and discrete variables; see Section 3.3 for details.

**Property specification**  In this model, the correctness property is that two processes cannot be in the critical section at the same time; as explained above, this is equivalent to the fact that the `obs_violation` location of the observer IPTA is unreachable. This is input in the model as follows:

```
property := unreachable loc[observer] = obs_violation;
```

More elaborate properties are detailed in Section 4.6 (however, they all reduce to reachability, so more complex properties such as Büchi-like properties or fairness are not yet supported by IMITATOR).

**Parameter synthesis**  Finally, let us run IMITATOR on this case study. Quite naturally, what we would be interested in is knowing for which parameter valuations this protocol is correct, i.e., no more than one process can be present in the critical section at one time. Assuming this model is input in file `fischer.imi`, the command calling IMITATOR is as follows:

```
$ ./imitator fischer.imi -mode EF -merge
```

In this command, `-mode EF` calls the algorithm EFsynth that synthesizes valuations reaching a given location (see Section 4.2); and `-merge` is a merging technique reducing the state space that, for this model, ensures termination (see [AFS13] for more details on merging).

The result of the call to IMITATOR is

```
Final constraint such that the system is correct:
delta >= 0
& gamma > delta
This good constraint is exact (sound and complete)
```

That is, the system is safe if \( 0 \leq \delta < \gamma \), which is the well-known constraint ensuring mutual exclusion for this protocol.
Chapter 3

IMITATOR Parametric Timed Automata

This chapter formally introduces the input model of IMITATOR.

3.1 Formal definition

IMITATOR performs parametric verification of models specified using networks of IMITATOR parametric timed automata (hereafter NIPTA).

An IMITATOR parametric timed automaton (hereafter IPTA) is a variant of parametric automata (as introduced in [AHV93]). A first difference between IPTA and the PTA of [AHV93] is that IPTA have no accepting / final location; furthermore, IPTA augment the expressiveness of PTA with several features such as invariants, discrete (rational) variables, complex guards and invariants (i.e., not only comparing a single clock to a single parameter), stopwatches (i.e., the ability to stop some clocks in some locations), and arbitrary clock updates (i.e., not necessarily to 0).

3.1.1 Clocks, parameters, discrete variables

Clocks are real-valued variables all evolving at the same rate (unless they are stopped, which is allowed in IMITATOR). A set of clocks is $X = \{x_1, \ldots, x_H\}$; a clock valuation is $w: X \rightarrow \mathbb{R}_{\geq 0}$.

Parameters are rational-valued variables, that act as unknown constants. A set of parameters is $P = \{p_1, \ldots, p_M\}$; a parameter valuation is a function $v: P \rightarrow \mathbb{R}$. We will often identify a valuation $v$ with the point $(v(p_1), \ldots, v(p_M))$.

Discrete variables are rational-valued variables. A set of discrete variables is $D = \{d_1, \ldots, d_J\}$; a discrete variable valuation is a function $\delta: D \rightarrow \mathbb{N}$.

3.1.2 Linear constraints

Let us formalize the set of linear constraints allowed in IMITATOR. Given a set of variables $Var = \{z_1, \ldots, z_N\}$ (in the following, this set will be instantiated with $X$ and/or $P$ and/or
D), a linear term over Var is an expression of the form

$$\sum_{1 \leq i \leq n} \alpha_i z_i + d$$

for some $n \in \mathbb{N}$, where $z_i \in \text{Var}$, $\alpha_i \in \mathbb{Q}$, for $1 \leq i \leq n$, and $d \in \mathbb{Q}$.

An atomic constraint over Var is an expression of the form $lt \triangledown 0$ where $lt$ is a linear term over Var, and $\triangledown \in \{<, \leq, =, \geq, >\}$.

A constraint over Var is a conjunction of atomic constraints. We denote by $\mathcal{L}(\text{Var})$ the set of linear terms over Var, and by $\mathcal{LC}(\text{Var})$ the set of constraints over Var. In IMITATOR, we will consider constraints belonging to sets such as $\mathcal{LC}(X \cup P \cup D)$ (i.e., the set of constraints over clocks, parameters, and discrete variables).

### 3.1.3 Arithmetic expressions

Let $\mathcal{AE}(D)$ denote the set of arithmetic expressions over the discrete variables, i.e., made of addition, subtraction, multiplication, and division over rational (or integer) constants and discrete variables.

### 3.1.4 IMITATOR Parametric Timed Automata

We can now give a formal definition of IPTA.

Let $\epsilon$ denote the unobservable action.

**Definition 3.1 (IPTA).** An IMITATOR parametric timed automaton (IPTA) is a tuple $\mathcal{A} = \langle \Sigma, L, \ell_{\text{init}}, D, X, P, I, S, \rightarrow \rangle$, where:

- $\Sigma$ is a finite set of actions;
- $L$ is a finite set of locations;
- $\ell_{\text{init}} \in L$ is the initial location;
- $D$ is a set of rational-valued variables;
- $X$ is a set of clocks;
- $P$ is a set of parameters;
- $I : L \rightarrow \mathcal{LC}(X \cup P \cup D)$ assigns to every location $\ell$ a constraint over all variables, called the invariant of $\ell$;
- $S : L \rightarrow X$ assigns to a every location a list of clocks that are stopped in this location;
- $\rightarrow$ is a set of edges $\langle \ell, g, a, X_{\text{up}}, D_{\text{up}}, \ell' \rangle$, where $\ell, \ell' \in L$ are the source and destination locations, $g \in \mathcal{LC}(X \cup P \cup D)$ is a constraint over all variables (called guard of the transition), $a \in \Sigma \cup \{\epsilon\}$ is the action associated with the transition,
\[ X_{up} : X \to \mathcal{F} (X \cup P \cup D) \] is the (possibly partial) update function for clocks, and
\[ D_{up} : D \to \mathcal{E} (D) \] is the (possibly partial) update function for discrete variables.

In the following, we explain this definition.

**Guards and invariants** Guards and invariants in IMITATOR are linear constraints over all variables. For example, the following expression can be used in a guard or an invariant:

\[ i_1 + .5 x_1 + 3 x_2 \geq 2 p_1 - i_2 \land p_2 < 1/3 \]

where \( i_1, i_2 \) are discrete variables, \( x_1, x_2 \) are clocks and \( p_1, p_2 \) are parameters. This syntax includes in particular diagonal constraints (e.g., \( x_1 - x_2 \leq 2 \)), not always supported in other model-checking tools.

**Actions** Transitions can be synchronized on an action in \( \Sigma \), or have no synchronized action (“\( \epsilon \)”), which is often referred to in the literature as a silent transition, or an \( \epsilon \)-transition. For the semantics of the synchronization model between various IPTA, refer to Section 3.4. A non-silent transition is said to be *observable*, and it can be synchronized with other automata.

**Clock updates** Observe that clocks can be updated to any value, *i.e.*, a clock can be assigned not only to 0, but to any linear term over the other clocks, the parameters and the discrete variables. This considerably extends the traditional syntax of PTAs defined in [AHV93]. In fact, the IMITATOR includes (more than just) the updatable timed automata of [Bou+04], as well as the reset-to-parameter (parametric) timed automata of [ALR18b]. If clocks are always reset to constants (*i.e.*, not assigned to more complex linear terms), IMITATOR will apply some optimizations that (may) increase the analysis speed.

**Discrete updates** Discrete variables can be assigned to arithmetic expressions over \( D \). On the one hand, this is more restrictive than clock updates, because discrete variables cannot be assigned to a clock or to a parameter. On the other hand, arithmetic expressions are richer than linear constraints, as they allow multiplication or division of variables with each other.

Since version 2.12, **if-then-else** conditions are allowed in *discrete* updates.

**Stopwatches** There are no distinction between clocks and stopwatches. That is, any clock can potentially be stopped in some location. IMITATOR will detect whether a model has or not stopwatches; if there is no stopwatch in some model, IMITATOR will apply some optimizations that (may) increase the analysis speed.

### 3.1.5 Networks of IMITATOR Parametric Timed Automata

**Definition 3.2** (NIPTA). Given a set of IPTA \( \mathcal{A}_i = \langle \Sigma_i, L_i, (L_{init})_i, D_i, X_i, P_i, I_i, S_i, \rightarrow_i \rangle \), \( 1 \leq i \leq N \) for some \( N \in \mathbb{N} \), a network of IPTA (NIPTA) is a tuple \( \langle \Sigma, D, X, P, \{ \mathcal{A}_i \mid 1 \leq i \leq N \}, C_{init} \rangle \), where:

- \( \Sigma = \bigcup_{1 \leq i \leq N} \Sigma_i \) is the set of all actions;

---

14
• $D = \bigcup_{1 \leq i \leq N} D_i$ is the set of all discrete variables;
• $X = \bigcup_{1 \leq i \leq N} X_i$ is the set of all clocks;
• $P = \bigcup_{1 \leq i \leq N} P_i$ is the set of all parameters;
• $C_{\text{init}} \in \mathcal{L}(X \cup P \cup D)$ is the initial constraint over $D$, $X$ and $P$.

Observe that each set of actions, discrete variables, clocks and parameters is not disjoint between all IPTA. That is, actions, discrete variables, clocks and parameters may be shared between different IPTA. If a variable is required to be local to an IPTA, then it should just not be used in any other IPTA of the model.

Different from many tools for (parametric) timed automata, clocks are not necessarily initially equal to 0 (this is similar to HyTech [HHW95] but different from UPPAAL [LPY97]). The initial value of the clocks is defined by $C_{\text{init}}$ (see Section 3.3). If nothing is defined in $C_{\text{init}}$, then their value is supposed to be arbitrary (any real value greater or equal to 0).

Note that parameters are not assumed positive; however, the behavior of IMITATOR has not been tested for negative parameters, and it is strongly advised to constrain them to be positive in $C_{\text{init}}$ (if it is not the case, a warning is issued by IMITATOR).

Finally, note that the number of IPTA, locations, variables and actions that can be defined in a model is bounded in IMITATOR by some very large number (most probably $2^{32}$); but, well, you don’t seriously plan to build such a large model, do you?

IMITATOR may use the determinism in (yet to come) algorithms; and the deterministic nature of an NIPTA is detected by IMITATOR. In our setting, the strong determinism denotes at most one transition going out from a location and labeled with a given observable (i.e., non-silent) transition. Let us precisely define what it means:

**Definition 3.3** (strong determinism). Let $\mathcal{A}$ be an NIPTA made of $N$ IPTA $\mathcal{A}_i = \langle \Sigma_i, L_i, (\ell_{\text{init}})_i; D_i, X_i, P_i, I_i, S_i, \rightarrow_i \rangle$, $1 \leq i \leq N$ for some $N \in \mathbb{N}$.

$\mathcal{A}$ is strongly-deterministic if for all automaton $\mathcal{A}_i$, for all location $\ell_i \in L_i$, for all observable action $a \in \Sigma_i$, there exists at most one transition from $\ell_i$ labeled with $a$.

### 3.2 Discrete variables

Discrete variables\(^1\) are global rational-valued variables. Their value is global, in the sense that they are shared by all IPTA of the model. They can be seen as syntactic sugar to represent a possibly unbounded number of locations.

In IMITATOR, rationals are exact and unbounded, just as in maths (i.e., they are not represented using a limited number of bits, such as 32 or 64 bits). Hence, no overflow can occur, and the representation of the constraints is always exact. Note that floating-point numbers are totally absent from the IMITATOR implementation (except for the generation of graphical outputs).

\(^1\)The name “discrete variable” comes from HyTech.
Discrete variables must be initialized to a single constant value in the `init` definition; if they are not, a warning is issued, and they are arbitrarily set to 0.

Discrete variables can be tested in guards, and updated along transitions. They are first tested, then updated. If two IPTA in parallel update the same variable on the same synchronized transition (e.g., an IPTA performs `i := 2` while another one performs `i := 3`), then a warning is issued, and the behavior of the NIPTA becomes unspecified (i.e., IMITATOR will choose one or the other assignment in a non-deterministic manner). If a division by zero is encountered (e.g., in an update `i := 2 / i`, when the current value of `i` is 0), an exception is raised and IMITATOR terminates with an error.

### 3.3 Initial state and initialization of variables

For each IPTA, a unique initial location must be defined.

For variables, the definition of the initial value is very permissive in IMITATOR. Clocks are not necessarily equal to 0, and parameters are not even necessarily positive.

Parameters and clocks can be initially bound by any linear constraint over parameters, clocks, and discrete variables. That is, we can define initial constraints such as:

\[ x_1 + x_2 \leq 2 \ p_1 + 0.5 \ p_2 - i. \]

However, discrete variables must be initialized to a *constant rational*. Given a discrete variable `i`, if the definition of the initial state does not contain an equality of the form `i = ...` followed by a linear term in `L(T)(D)`, then IMITATOR will assume that `i` is initially set to 0, and will issue a warning.

### 3.4 Synchronization model

By default, all IPTA of an IMITATOR model declare their set of actions.\(^2\)

The IMITATOR synchronization model is such that all IPTA declaring an action must synchronize together on this action. This can be seen as a *strong broadcast*. That is, for a transition labeled with action `a` to be executed, all IPTA declaring `a` must be ready to execute `a` locally. Otherwise, this transition cannot be taken (yet).

If an IPTA declares an action `a` that is never used in this IPTA, then action `a` will never be executed in the entire model.\(^3\)

### 3.5 Constants

IMITATOR supports global constants, *i.e.*, a variable the value of which is known once for all. The syntax is the following one:

\[ c = 1: \ constant; \]

\(^2\)An alternative is an automatic recognition of the actions used, see option `-sync-auto-detect` in Chapter 8.

\(^3\)In this case, IMITATOR will detect this situation and will entirely delete this action from the model, while issuing a warning.
Then, any occurrence of \( c \) in the model is replaced with 1.

Constants are (unbounded, exact) rationals.

Limited linear expressions over rationals can be used in the definition of a constant; however no other constant can be used in a definition, \textit{i.e.}, one cannot (yet) write \( c_1 = c_2 + 1 \):

```
constant;
```

\textit{Hint 3.1.} In fact, a variable (\textit{e.g.}, a parameter) can be turned to a constant as follows in the definition of the parameters:

```
p = 2: parameter;
```

This is equivalent to replacing \( p \) with 2 everywhere in the model; this is particularly useful when some parameters should be instantiated. In contrast, if the parameter is instantiated in the initial definition, IMITATOR still counts it as a parameter, which makes all constraints suffer from an additional dimension.
Chapter 4

Parameter synthesis using IMITATOR

We give here the commands corresponding to the main analysis features of IMITATOR. We only give the most useful options. For more detailed commands, and a complete list of options, see Chapter 8.

4.1 Symbolic state space computation

IMITATOR can compute the entire symbolic state space ("parametric zone graph"). Of course, the state space may be infinite, and this analysis is not guaranteed to terminate.

The standard command is:

```
$ ./imitator model.imi -mode statespace -output-states
```

The option \texttt{-output-states} generates a file with a textual description of all states (without this option, IMITATOR will not output anything). Each state is represented with its discrete part (location and values of the discrete variables), the clock and parameter constraints, and below their projection onto the parameters; in addition, if \texttt{projectresult} is defined in the model (see Section 5.5), the projection onto a specific set of parameters is also added.

IMITATOR can also output the trace set in a graphical form using option \texttt{-output-trace-set}.

4.2 EF-synthesis

4.2.1 Reachability

A main problem in parametric timed automata is to compute the set of parameter valuations for which some location (for instance, an error location) is reachable.

The property must be specified as follows, at the end of the model (after the initial state definition):

```
  property := unreachable loc[AUTOMATON] = LOCATION;
```

where \texttt{AUTOMATON} is an automaton name, and \texttt{LOCATION} is a location name.
The algorithm EFsynth implemented in IMITATOR is a basic breadth-first procedure, close to the one described in [JLR15]. Of course, the EF-emptiness problem being undecidable [AHV93], the analysis is not guaranteed to terminate.

The standard command is:

```
$ ./imitator model.imi -mode EFunsafe -merge -incl -output-result
```

The option `-output-result` is not compulsory, but allows one to obtain a result in an external text file (`model.res`) formatted using a standardized manner (see Chapter 5), and therefore easier to parse using an external tool than the terminal output.

The options `-merge` and `-incl` are optional, but generally greatly increase the analysis efficiency and the termination. The option `-dynamic-elimination` can also be used to reduce the state space.

IMITATOR can also output the trace set in a graphical form (option `-output-trace-set`), output the constraint synthesized in a graphical form in two dimensions (option `-output-cart`), or output the result to a text file using a normalized syntax (option `-output-result`), that can be then scripted from external programs.

### 4.2.2 Safety

Often, we are rather interested in safety synthesis, i.e., the set of valuations for which the target location is unreachable.

The standard command is:

```
$ ./imitator model.imi -mode EFsynth -merge -incl -output-result
```

Internally, this algorithm works exactly the same as the reachability-synthesis, and at the end the obtained constraint is negated (with parameters being constrained to be included in the initial state valuations).

**Remark 4.1.** For both reachability and safety, one can use the option `-counterexample` to stop the analysis as soon as a counterexample is found (see list of options in Chapter 8).

In that case, the result is not exact, but approximated.

### 4.3 EF-minimization

This algorithm synthesizes the minimum valuation for a given parameter for which a given location is reachable. The property must be specified as for EFsynth (see Section 4.2). This algorithm is briefly mentioned in [And+19].

In addition, the parameter to be minimized must be specified at the end of the model as follows:

```
minimize(parameter_name)
```

The standard command is:

```
$ ./imitator model.imi -mode EFmin -merge -incl -output-result
```
4.4 EF-maximization

This algorithm is the dual of EF-minimization (see Section 4.3).

The parameter to be maximized must be specified at the end of the model as follows:

\[
\text{maximize} (\text{parameter\_name})
\]

The standard command is:

\[
./imitator\ model.imi \ -mode\ EFmax\ -merge\ -incl\ -output\_result
\]

4.5 EF with optimal time reachability

This algorithm synthesizes the parameter valuations for which a given location is reachable in minimal time [And+19]. The property must be specified as for EFsynth (see Section 4.2).

Our algorithm uses a priority queue, with priority to the earliest successor for the selection of the next state.

The standard command is:

\[
./imitator\ model.imi\ -mode\ EFsynthminpq\ -merge\ -incl\ -output\_result
\]

4.6 Parameter synthesis using properties

IMITATOR basically only supports bad state reachability synthesis on the one hand, and algorithms such as the inverse method and the cartography on the other hand. However, many correctness properties can be encoded using reachability using observers (see [ABL98; Ace+98; Ace+03; And13b]).

Encoding observers can be done manually (using ad-hoc IPTA), or using predefined correctness properties commonly met in the literature.

If using a predefined property, the property must be specified as follows, at the end of the model (after the initial state definition):

\[
\text{property} := [PROP]
\]

[PROP] must conform to one of the following patterns, where AUTOMATON is an automaton name, LOCATION is a location name, a, a1, a2 are actions, and the deadline d is a (possibly parametric) linear expression:

- property := unreachable loc[AUTOMATON] = LOCATION
- property := if a2 then a1 has happened before
- property := everytime a2 then a1 has happened before
- property := everytime a2 then a1 has happened once before
- property := a within d
- property := if a2 then a1 has happened within d before
- property := everytime a2 then a1 has happened within d before
• property := everytime a2 then a1 has happened once within d before
• property := if a1 then eventually a2 within d
• property := everytime a1 then eventually a2 within d
• property := if a1 then eventually a2 within d once before next
• property := sequence a1, ..., an
• property := always sequence a1, ..., an

The semantics of these properties is detailed in [And13b].
Then, the command to synthesize parameters is the same as for the EF-synthesis:

$ ./imitator model.imi -mode EFsynth -merge -incl -output-result

Once more, options -merge and -incl are optional, but often improve efficiency and termination.

4.7 Parametric deadlock-freeness checking

Given an NIPTA, PDFC synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the system is deadlock-free [And16].

The command is:

$ ./imitator model.imi -mode PDFC -output-result

As usual, IMITATOR can also output the trace set in a graphical form (option -output-trace-set) or output the constraint synthesized in a graphical form in two dimensions (option -output-cart).

4.8 Parametric cycle synthesis

4.8.1 Any loop synthesis

Given an NIPTA, IMITATOR synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the system contains at least one cycle, i.e., an infinite run.

The command is:

$ ./imitator model.imi -mode LoopSynth -output-result

As usual, IMITATOR can also output the trace set in a graphical form (option -output-trace-set) or output the constraint synthesized in a graphical form in two dimensions (option -output-cart).
4.8.2 Accepting loop

Given an NIPTA, IMITATOR synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the system contains at least one accepting cycle, i.e., an infinite run passing infinitely often by an accepting location.

The accepting location is defined as usual using the following syntax:

\[
\text{property} := \text{unreachable loc[pta]} = \ldots;
\]

...which can be misleading as the property is defined using unreachable while the location should actually be reachable. Patterns (see Section 4.6) can also be used.

The command for accepting cycle synthesis is:

$./imitator model.imi -mode AccLoopSynth -output-result

4.8.3 Accepting loop (NDFS)

Given an NIPTA, IMITATOR synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the system contains at least one accepting cycle. This algorithm differs from the one in Section 4.8.2 in the sense that this algorithm performs a nested depth-first search (NDFS) exploration until a cycle is found [NPV18]. In addition, this algorithm is (by default) not complete.

The command is:

$./imitator model.imi -mode AccLoopSynthNDFS -output-result

Several heuristics can be used, some of them synthesizing all parameter values for which a cycle can be found. These are accessible via the -explOrder option:

- explOrder NDFS : use standard NDFS to find an accepting cycle (default option);
- explOrder NDFSsub : standard NDFS with subsumption;
- explOrder layerNDFSsub : NDFS with subsumption and layers;

At each cycle found, IMITATOR outputs its number (when using the synthesis) and the node at which the cycle was detected. When it terminates the complete parameter constraint is displayed.

When using the -depth-limit option, the depth-first search stops exploring the current branch and backtracks when this depth is reached.

As usual, IMITATOR can also output the trace set in a graphical form (option -output-trace-set) or output the constraint synthesized in a graphical form in two dimensions (option -output-cart).

Remark 4.2. As for EFsynth, one can use here the option -counterexample to stop the analysis as soon as a counterexample is found (see list of options in Chapter 8).
4.9 Parametric non-Zeno cycle synthesis

Given an NIPTA, IMITATOR synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the system contains at least one cycle, under the non-Zeno assumption [And+17]. That is, only parameter valuations yielding at least one non-Zeno cycle are synthesized. Parameter valuations yielding only Zeno-cycles or no cycles are ignored.

The method implemented in IMITATOR is based on CUB-IPTA, a syntactic subclass of PTA based on the CUB-TA proposed in [Wan+15].

Two options are possible in IMITATOR:

1. a partial method (but slightly faster) than first detects whether the input NIPTA is already a CUB-PTA; if so, it applies non-Zeno checking on this CUB-PTA; otherwise, the returned constraint will be false.
   
   $ . /imitator model.imi -mode NZCUBcheck -output-result$

2. a complete method (though of course without guarantee of termination), that transforms the NIPTA into a network of CUB-PTAs, and applies non-Zeno checking on the transformed CUB-PTA.

   $ . /imitator model.imi -mode NZCUBtrans -output-result$

**Warning 1 (restrictions).** In contrast to most other algorithms of IMITATOR, these two algorithms work on a slightly restricted syntax:

- in a guard or invariant, each clock must be used at most once;
- the conditional updates (new since version 2.12) are not supported;
- the use of discrete variables was not tested (and may not be always working);
- the use of coefficients on parameters (different from 0 or 1) was not tested;
- the use of stopwatches was not tested (but should be no problem).

Overall, this part of IMITATOR has been less tested and is probably less stable than the rest of the tool.

As usual, IMITATOR can also output the trace set in a graphical form (option `-output-trace-set`) or output the constraint synthesized in a graphical form in two dimensions (option `-output-cart`).

**Remark 4.3.** The accepting cycles are not (yet?) supported for non-Zeno synthesis.
4.10 Inverse method: Trace preservation and robustness

Given an NIPTA and a reference parameter valuation, the inverse method IM synthesizes a parameter constraint such that, for any parameter valuation in that constraint, the set of traces is the same as for the reference valuation [And+09]. This problem is known as the trace-preservation synthesis, and formalized in [AM15]. The trace-preservation emptiness problem being undecidable [AM15], the analysis is not guaranteed to terminate (although it often does in practice).

The command is:

```
./imitator model.imi model.pi0 -output-result
```

The reference valuation is described in `model.pi0`.

IMITATOR can also output the trace set in a graphical form (option `-output-trace-set`) or output the constraint synthesized in a graphical form in two dimensions (option `-output-cart`).

Recall that the option `-output-result` is not compulsory, but allows one to obtain a result in an external text file (`model.res`) and formatted using a standardized manner (see Chapter 5).

4.11 Behavioral cartography

Given an NIPTA and a bounded parameter domain, the behavioral cartography BC synthesizes tiles, i.e., parameter domains such that for any parameter valuation in that domain, the set of traces is the same [AF10]. The corresponding problem being undecidable, the analysis is not guaranteed to terminate; when it terminates, it may also leave “holes”, i.e., parameter domains not covered by any tile.

The command is:

```
./imitator model.imi model.v0 -mode cover -output-result
```

The bounded parameter domain is described in `model.v0`.

IMITATOR can also output all trace sets in a graphical form (option `-output-trace-set`), output the constraints synthesized in a graphical form in two dimensions (option `-output-cart`), or output the result to a text file using a normalized syntax (option `-output-result`).

The option `-step` specifies the interval between any two points of which the coverage is checked (see [AF10]). By default, it is 1; setting $\frac{1}{3}$ often leads to full coverage when 1 was not enough.

In addition, trace sets and separate graphical cartographies for each tile can also be generated by adding option `-output-tiles-files`.

Recall that the option `-output-result` is not compulsory, but allows one to obtain a result in an external text file (`model.res`) formatted using a standardized manner (see Chapter 5), and therefore easier to parse using an external tool than the terminal output.
Behavioral cartography with random coverage

An alternative to the behavioral cartography is a random coverage; it can be seen as a kind of sampling.

The command is:
```
$ ./imitator model.imi model.v0 -mode randomXX -output-result
```
where $XX$ is the number of times an integer point is randomly selected within the domain defined in `model.v0`. If this point is already covered by one of the tiles, the inverse method is not called, an another point is selected. Note that $XX$ represents the number of integer points randomly selected; the number of calls to the inverse method can be significantly smaller.

Behavioral cartography with shuffle enumeration

A second alternative to the behavioral cartography is an enumeration of all integer points in a random fashion. That is, all integer points in the reference parameter domain are generated in a data structure (an array), and then are shuffled. Then the points are enumerated. It differs from the random cartography in the sense that the random cartography randomly samples points without guarantee of full coverage, whereas the shuffle enumeration guarantees the coverage of all integer points.

The command is:
```
$ ./imitator model.imi model.v0 -mode shuffle -output-result
```

4.12 Parametric reachability preservation

IMITATOR implements an algorithm solving the following problem: “given a reference parameter valuation $v$ and some location $\ell$, synthesize other valuations that preserve the reachability of $\ell$”. By preserving the reachability, we mean that $\ell$ is reachable for the other valuations iff $\ell$ is reachable for $v$.

This algorithm PRP, that combines EFsynth and IM (see [And+15] for details), is called as follows:
```
$ ./imitator model.imi model.pi0 -mode PRP -output-result
```

Note that a bad location (as in Section 4.2) or a property (as in Section 4.6) must be defined in the model.

Parametric reachability preservation cartography

An extension of PRP to the cartography (named PRPC) is also available: PRPC synthesizes parameter constraints in which the (non-)reachability of $\ell$ is uniform. PRPC was showed in [And+15] to be a good alternative to EFsynth, especially when distributed (see option -distributed).

This algorithm PRPC is called as follows:
```
$ ./imitator model.imi model.v0 -mode PRPC -output-result
```

Again, a bad location (as in Section 4.2) or a property (as in Section 4.6) must be defined in the model.
Chapter 5

Understanding the IMITATOR result

Using option `-output-result`, IMITATOR generates a file `model.res`. Since version 2.7, this file has a standardized format, and can therefore be parsed using an external tool.

We do not give a formal grammar for this file (yet), but it can be easily inferred from example outputs.

5.1 Header

The file header recalls the exact version of IMITATOR used to run the analysis, including the build number, the git branch and the git SHA hash. It also recalls the model name, the exact command used, and the time when the file was generated (which may slightly differ from the time the analysis was run, if the analysis was significantly long).

Then, the header recalls global information on the model (number of IPTA, of clocks, of parameters, whether the model contains stopwatches, etc.).

5.2 The resulting constraint

The main result of a single synthesis (i.e., EFsynth, PDFC, IM and its variants, PRP...) is a constraint. This result is clearly delimited by delimiters `BEGIN CONSTRAINT` and `END CONSTRAINT`.

The result can be a convex or a non-convex constraint. In some cases, the result is made of two (convex or non-convex) constraints: a good constraint (characterizing good parameter valuations), and a bad constraint (characterizing bad parameter valuations). Both parts of the results are then separated using the keyword `<good | bad>` (of course the good constraint comes left of this separator, and the bad constraint comes right).

The resulting constraint comes with two other information:

- its nature, i.e., whether it attempts to characterize a good set of valuations, a bad set of valuations, or both a good set and a bad of valuations. “Good” and “bad” must be understood to the property that is being checked (non-reachability of some states, deadlock-freeness, etc.). The constraint nature is only an attempt, as the constraint may not always be sound (see below).
• its soundness, *i.e.*, whether the constraint is exact (IMITATOR returned exactly the set of parameter valuations solution to the analysis requested), a possible under-approximation of that result, a possible over-approximation of that result (in some rare cases), or a possibly invalid constraint (in which case the result output by IMITATOR shall not be used).

Note that in almost all analyses, IMITATOR return an exact or an under-approximated constraint. A possibly invalid constraint can be synthesized when some options are used: for example, computing the result of IM with the merging enabled (`-merge`) yields a possibly invalid constraint, as it was shown that the merging optimization does not preserve the validity of the result of IM [AFS13].

**Remark 5.1.** IM is independent of the property, and therefore the constraint nature is not really interesting. IMITATOR performs the following: if a safety property is defined and if the state space reaches some unsafe states, then the constraint is considered as bad. In any other case (safe state space, or no safety property defined), the constraint nature is considered as good. The same applies for BC.

Finally, the result also comes with an evaluation of the termination: the termination can be regular (the analysis went to its end without interruption) or an early termination, with some states unexplored (*e.g.*, if a maximum analysis time (`-time-limit`), a maximum exploration depth (`-depth-limit`), etc., was set).

### 5.3 The cartography result

The behavioral cartography does not strictly speaking generate a result, but a list of tiles: each of them is made of the reference valuation that yielded that tile, the associated constraint again with its nature, its soundness, and the analysis termination. In addition, each tile comes with its associated number of states and transitions, and its computation time.

### 5.4 General statistics

The result file finally contains general statistics such as the global computation time (excluding the generation of graphics, or the result file), an estimation of the memory used, the number of states and transitions computed, etc. Finally, some statistics on specific operations (model parsing, graphics drawing, etc.) are given. More statistics are obtained with higher levels of verbosity, or with the `-statistics` option.

### 5.5 Projection onto some parameters

The result can be projected onto selected parameters, by using the following syntax at the end of the model file:

```
projectresult(param1, ..., paramn);
```

In that case, all parameters not in that set are eliminated using variable elimination, and the result in the result file only contains the selected parameters.
This projection is also added to the states description (see option `-output-states`) and to the graphical state space output (see option `-output-trace-set-verbose`).
Chapter 6

Graphical output and translation

Again, we only give the most useful options. For more detailed commands, and a complete list of options, see Chapter 8.

6.1 Trace set

To generate the trace set (i.e., the discretized state space) of a given computation in a graphical form, use:

```bash
$ ./imitator model.imi [options] -output-trace-set
```

IMITATOR will generate a file `model-statespace.pdf`. States are made of two part: the left-hand number (e.g., `s_0`) is the number of the symbolic state, which comes from IMITATOR internal representation (e.g., `s_0` is the first one to be generated, and so on); the right-hand part displays all the discrete part of the symbolic state vertically, that is the current location in each of the NIPTA in parallel, and the value of possible discrete variables (if any). Consider state `s_1` in Fig. 6.1b (and originating from the example in Chapter 2): the current location of IPTA `proc_1` is `active1`, the current location of IPTA `proc_2` is `idle2`, while the current location of IPTA `observer` is `obs_waiting`. In addition, the current value of variable `turn` is −1 while the current value of `counter` is 0. The color is chosen according to IMITATOR internal choice: however, two symbolic states with the same color have the same discrete part (location and values of the discrete variables). For example, this is the case of `s_4` and `s_5` in Fig. 6.1b.

Note that, beyond about 1,000 states or 1,000 transitions, the dot utility (responsible to generate the state space) may crash.

Using `-output-trace-set-nodetails` makes a more compact representation, but is also less informative as only the state number and the transition labels are shown.

Conversely, `-output-trace-set-verbose` makes a more detailed representation, by also adding to the state space all constraints: the clock and parameter constraints, and below their projection onto the parameters; in addition, if `projectresult` is defined in the model (see Section 5.5), the projection onto a specific set of parameters is also added. This option is mostly suitable for small trace sets.
Example 6.1. An example of state space with no details (output using 
-\textit{output-trace-set-nodetails}), with normal details (using \textit{-output-trace-set}), 
and in verbose mode (using \textit{-output-trace-set-verbose}) are given in Figs. 6.1a 
to 6.1c.

These graphics were generated using the example in Chapter 2 with the following 
command:

\$ \textit{imitator fischer.imi -mode EF -depth-limit 4 -output-trace-set} 
(where \textit{-output-trace-set} should be replaced with the proper option)

6.2 Constraints and cartography

To visualize the constraint generated by IMITATOR using a 2-dimensional plot (thanks to the 
external plot utility), use:

\$ ./imitator model.imi [options] \textit{-output-cart} 

This will generate file \textit{model\_cart.png}.

The two dimensions chosen for the plot are the first two (non-constant) parameter di-
mension in the model.

Additional useful options are \textit{-output-cart-x-min}, \textit{-output-cart-x-max}, 
\textit{-output-cart-y-min}, \textit{-output-cart-y-max} to tune the values of the axes, and
\textit{-output-graphics-source} to keep the plot source.

6.3 Translation to UPPAAL

Since version 2.11, IMITATOR supports a translation of the model to the UPPAAL syn-
tax [LPY97]. To generate an equivalent UPPAAL model without performing any analysis, use:

\$ ./imitator model.imi \textit{-PTA2Uppaal} 

IMITATOR will generate a file \textit{model\_uppaal.xml}. Note that translation of properties is not 
supported.

Due to the different semantics and features between IMITATOR and UPPAAL, the trans-
lation is done in a “best effort” manner, but the semantics may differ. We review some points 
in the following.

Parameters A fundamental difference IMITATOR and UPPAAL is that UPPAAL does not sup-
port timing parameters. Parameters are therefore translated to constants, the value of which 
can be manually changed by the user.

Form of the constraints IMITATOR allows a much wider form of constraints than UPPAAL. 
In particular, IMITATOR allows any conjunction of linear constraints (see Section 3.1.2) while 
UPPAAL mainly allows clocks to be compared to integers. In addition, UPPAAL only allows in-
variants of the form $x \leq c$ or $x < c$, which is not a restriction in IMITATOR. No check are made
Figure 6.1: Examples of graphical state space
when translating, and therefore UPPAAL may not accept models translated from IMITATOR input models using these features.

**Discrete variables** Discrete variables in IMITATOR are rational-valued with an exact value. In UPPAAL, they are interpreted as (bounded) integers: overflows may occur and, if their value becomes non-integer, it seems UPPAAL will just round them to the nearest integer, thus creating a difference in semantics.

**Strong broadcast synchronization** IMITATOR uses a single communication model: strong broadcast (see Section 3.4), while UPPAAL uses both channel binary synchronization, and broadcast synchronization. None of them match IMITATOR’s semantics. Our translation tries to preserve IMITATOR semantics, using the following scheme:

- Unnamed actions (necessarily used in a single IPTA) remain unnamed in UPPAAL.
- An action $a$ used in a single IPTA is implemented in UPPAAL using a broadcast action $a!$.
- An action $a$ used in exactly two IPTA is implemented in UPPAAL using a binary action $a$, where the first (i.e., declared first in the IMITATOR file) uses $a!$ while the second uses $a?$.
- An action $a$ used in $n$ IPTA with $n \geq 3$ is implemented in UPPAAL using a broadcast action $a$ and an additional variable $nb\_a$ initially set to $n$, and that will be responsible to check that all automata can indeed synchronize, as follows:
  - all invariants contain $nb\_a = n$
  - the first automaton (i.e., declared first in the IMITATOR file) involved in the synchronization synchronizes on $a!$ and performs $nb\_a := 1$;
  - all other automata involved in the synchronization perform $nb\_a := nb\_a + 1$.

From the UPPAAL official semantics, the discrete variables are updated by first executing the update label given on the $a!$ transition, and then the update labels given on the $a?$ for increasing, which guarantees the correctness of this construction. (This construction was suggested by Jiří Srba.)

However, a major difference (which may prevent UPPAAL to interpret the translated models) is that UPPAAL forbids guard on receiving actions (of the form $a?$). Therefore, translating an IMITATOR model where an action $a$ is used in two automata (or more) with guards on more than one transition will lead UPPAAL to not accept the model. A manual editing will be needed.

**Initial constraint** The initial constraint is *not* translated, except for the initial value of the discrete variables. Notably, the clocks are initially 0 in UPPAAL, which is not necessarily the case in IMITATOR.
Properties  Properties are so far not translated to UPPAAL.

6.4 Translation to HYTech

Since version 2.8, IMITATOR supports a translation of the model to the HYTech syntax [HHW95] (that is quite close to that of IMITATOR anyway). To generate an equivalent HYTech model without performing any analysis, use:

```
$ ./imitator model.imi -PTA2HyTech
```

IMITATOR will generate a file `model.hy`. Note that translation of properties is not supported.

6.5 Export to graphics

To generate a graphic representation of the NIPTA model without performing any analysis, use:

```
$ ./imitator model.imi -PTA2JPG
$ ./imitator model.imi -PTA2PDF
$ ./imitator model.imi -PTA2PNG
```

IMITATOR will generate a file `model-pta.jpg`, `model-pta.pdf` and `model-pta.png` respectively (using the `dot` utility).

Colored transitions are synchronized transitions (i.e., shared by at least two IPTA), black transitions are local transitions, while dotted transitions are unnamed local transitions (often referred to as $\varepsilon$-transitions in the literature).

**Example 6.2.** Consider again the case study given in Chapter 2 (and of which a TikZ export was given in Fig. 2.1). Then the result of the `-PTA2PDF` command is given in Fig. 6.2.

6.6 Export to \LaTeX

To generate a \LaTeX{} representation of the NIPTA model (using the `tikz` package) without performing any analysis, use:

```
$ ./imitator model.imi -PTA2TikZ
```

IMITATOR will generate a file `model.tex`. This file is a standalone \LaTeX{} file containing a single figure, which contains the different IPTA in “subfigure” environments. The node positioning is not yet supported (locations are depicted vertically), so you may need to manually position all nodes, and bend some transitions if needed.
Example 6.3. Consider again the case study given in Chapter 2: a TikZ export was given in Fig. 2.1, with some manual positioning.
Chapter 7

Inside the box

7.1 Language and libraries

In short, IMITATOR is written in OCaml, and contains about 26,000 lines of code. IMITATOR makes use of the following external libraries:

- The OCaml ExtLib library (Extended Standard Library for Objective Caml);
- The GNU Multiple Precision Arithmetic Library (GMP);
- The Parma Polyhedra Library (PPL) [BHZ08], used to compute operations on polyhedra.

7.2 Symbolic states

Verification of timed systems (and specially parametric timed systems) is necessarily done in a symbolic manner, in the sense that the timing information is abstracted by clock constraints. However, IMITATOR does not perform what is referred to as symbolic model checking; in other words, the representation of locations in IMITATOR is explicit (and not symbolic using, e.g., binary decision diagrams).

In short, a symbolic state in IMITATOR is made of the following elements:

- the current location (index) of each IPTA;
- the current value of the (rational-valued) discrete variables;
- a constraint on $X \cup P \cup D$ representing the continuous information.

In IMITATOR, all rationals (i.e., the value of the discrete variables and the coefficients used in the constraints) are unbounded rationals (implemented using GMP).

7.3 Installation

This document does not aim at explaining how to install IMITATOR. See the installation information available on the website for the most up-to-date information.
Binaries and source code packages are available on IMITATOR’s Web page [IMI-Web]. Several standalone binaries are provided for Linux systems, that require no installation.
Chapter 8

List of options

The options available for IMITATOR are explained in the following.

Note that some more options are available in the current implementation of IMITATOR. If these options are not listed here, they are experimental (or deprecated). If needed, more information can be obtained by contacting the IMITATOR team.

-acyclic (default: false) Does not test if a new state was already encountered. Without this option, when IMITATOR encounters a new state, it checks if it has been encountered before. This test may be time consuming for systems with a high number of reachable states. For acyclic systems, all traces pass only once by a given location. As a consequence, there are no cycles, so there should be no need to check if a given state has been encountered before. This is the main purpose of this option.

However, be aware that, even for acyclic systems, several (different) traces can pass by the same state. In such a case, if the -acyclic option is activated, IMITATOR will compute twice the states after the state common to the two traces. As a consequence, it is all but sure that activating this option will lead to an increase of speed.

Note also that activating this option for non-acyclic systems may lead to an infinite loop in IMITATOR.

-cart-tiles-limit <limit> (default: none) In cartography algorithm, set up a maximum of tiles to be generated by the algorithm.

-cart-time-limit <limit> (default: none) In cartography algorithm, set up a global time limit to the algorithm. In contrast, -time-limit is applied to each call to the inverse method.

-check-ippta (default: false) Check that every new symbolic state contains an integer point (i.e., a point in the \(X \cup P\) dimension). If not, raises an exception.

-check-point (default: false) In the inverse method, checks at each iteration whether the accumulated parameter constraint is restricted to the reference parameter valuation. Note that this option is not implemented as nicely as it could be, and can hence turn very costly.
-**contributors**  Print the list of contributors and exits.

-**counterexample**  For algorithms EFsynth and AccLoopSynthNDFS, stops the analysis as soon as one target state is found, and returns the (possibly approximated) result.

   This can be a way to solve the *emptiness* instead of the *synthesis* problem. Nevertheless, note that, instead of returning a Boolean answer, the algorithm still outputs some valuations (typically the valuations associated with the first parametric zone found, that allows to guarantee the violation of the property).

-**depth-limit <limit>** *(default: none)*  Limits the depth of the exploration of the state space. In the cartography mode, this option gives a limit to each call to the inverse method. Setting **depth-limit** guarantees the termination of any execution of IMITATOR, but not necessarily the correctness of the algorithms.

-**distributed <mode>** *(default: not distributed)*  Distributed version of the behavioral cartography. Various distribution modes are possible:

  - **no**  Non-distributed mode (default)
  - **static**  Static domain decomposition [ACN15];
  - **sequential**  Master-worker decomposition [ACE14];
  - **randomXX**  Master-worker scheme with random point distribution (e.g., random5 or random10); after XX successive unsuccessful attempts (where the generated point is already covered), the algorithm will switch to an exhaustive sequential iteration [ACE14];
  - **shuffle**  Master-worker scheme with shuffle point distribution [ACN15];
  - **dynamic**  Master-worker dynamic subdomain decomposition [ACN15];

-**dynamic-elimination** *(default: false)*  Dynamic elimination of clocks that are known to not used in the future of the current state [And13a].

-**explOrder**  Exploration orders are considered in two frameworks.

   First, for standard reachability analysis (and counterexample analysis, using **counterexample**), and documented in [ANP17]. This framework remains relatively experimental.

   Second, for accepting loop synthesis with NDFS exploration [NPV18] (see Section 4.8.3). In this latter case, the possible values are:

   - **explOrder NDFS** : use standard NDFS to find an accepting cycle (default option);
   - **explOrder NDFSsub** : standard NDFS with subsumption;
   - **explOrder layerNDFSsub** : NDFS with subsumption and layers;
-IMK (default: false)  When in mode inversemethod, uses a variant of the inverse method that returns a constraint such that no $\pi_0$-compatible state is reached; it does not guarantee however that any “good” state will be reached (see [AS13]).

-IMunion (default: false)  When in mode inversemethod, uses a variant of the inverse method that returns the union of the constraints associated to the last state of each path (see [AS13]).

-incl (default: false)  Consider an inclusion of parametric zone instead of the equality when performing the Post operation. In other terms, when encountering a new state, IMITATOR checks if the same state (same location and same constraint) has been encountered before and, if so, discards this “new” state. However, when the -incl option is activated, it suffices that a previous state with the same location and a constraint greater than or equal to the constraint of the new state has been encountered to discard the new state and stop exploring the current branch. This option corresponds to the way that, e.g., HyTech works, and suffices when one wants to check the non-reachability of a given bad state.

-incl2 (default: false)  Consider a bidirectional inclusion of parametric zone instead of the equality when performing the Post operation. When the -incl2 option is activated, it suffices that a previous state with the same location and a constraint greater than or equal to (resp. smaller or equal to) the constraint of the new state has been encountered to discard the new state (resp. the old state, which is replaced by the new one).

It seems that, although less states are computed, this option is less efficient than -incl (in part due to the extra inclusion checks required by -incl2).

-merge (default: false)  Use the merging technique of [AFS13]. This option is safe (and advised) for the EFsynth algorithm.

However, not all the properties of the inverse method are preserved when using merging (see [AFS13] for details).

-mode (default: inversemethod)  The mode for IMITATOR, i.e., the algorithm to run.

checksyntax  Simple syntax check and no analysis. Use option -output-result to generate a simple file with statistics on the model (numbers of variables, automata, L/U-nature, strong determinism...)

statespace  Generation of the entire parametric state space (see Section 4.1)

EF  Parametric reachability synthesis (EFsynth [JLR15]) (see Section 4.2)

EFmin  Parametric minimization synthesis (see Section 4.3)

EFmax  Parametric maximization synthesis (see Section 4.4)

EFsynthminpq  Minimal-time reachability synthesis [And+19] (see Section 4.5)
### Parameters

</table>

**-no-inclusion-test-in-EF** (default: false) In EFsynth, no inclusion test of the new states constraints in the already computed constraint is performed when this option is enabled. Otherwise, in normal mode, the algorithm checks whether a new state parameter constraint is included into the already computed parameter constraint and, if so, cuts the branch. This can save time by cutting branches, but can also slow down the analysis for complex constraints.

**-no-random** (default: false) In the inverse method, no random selection of the $\pi_0$-incompatible inequality (select the first found). By default, select an inequality in a random manner.

**-no-time-elapsing** (default: false) When computing a new symbolic state, compute the time elapsing before taking the transition instead of after.

**-no-var-autoremove** (default: false) Usually, IMITATOR automatically removes from the analysis the variables declared in the header, but used nowhere in the IPTAs nor in the correctness property. Note that a variable updated (to 0 or to any other value) is not considered used, as long as it is not used elsewhere (i.e., in a guard, an invariant, a value to be updated to,
a property...). Using `-no-var-autoremove` prevents IMITATOR from automatically remove these variables.

`-output-cart` *(default: off)*  
After execution of the behavioral cartography or EFsynth, plots the generated zones as a `.png` file. This will generate file `model_cart.png`. If the model contains more than two parameters, then `-output-cart` will plot the projection of the generated zones on the first two parameters of the model (or on the two `varying` parameters in the case of BC).

This option makes use of the external utility `graph`, which is part of the GNU plotting utils, available on most Linux platforms. The generated files will be located in the same directory as the source files, unless option `-output-prefix` is used.

Additional useful options are `-output-cart-x-min`, `-output-cart-x-max`, `-output-cart-y-min`, `-output-cart-y-max` to tune the values of the axes, and `-output-graphics-source` to keep the plot source.

`-output-cart-x-min` *(default: off)*  
Set minimum value for the $x$ axis when plotting the cartography (not entirely functional in all situations yet).

`-output-cart-x-max` *(default: off)*  
Set maximum value for the $x$ axis when plotting the cartography (not entirely functional in all situations yet).

`-output-cart-y-min` *(default: off)*  
Set minimum value for the $y$ axis when plotting the cartography (not entirely functional in all situations yet).

`-output-cart-y-max` *(default: off)*  
Set maximum value for the $y$ axis when plotting the cartography (not entirely functional in all situations yet).

`-output-float` *(default: false)*  
Convert (exact-valued) discrete variables into (possibly approximated) floats in all outputs.

`-output-graphics-source` *(default: false)*  
Keep file(s) used for generating graphical output (*e.g.*, trace set, cartography); these files are otherwise deleted after the generation of the graphics.

`-output-prefix` *(default: `<input_file>)*  
Set the path prefix for all generated files. The path can be either relative (to the path to the ./imitator binary) or absolute, and must be followed by the file name.

Examples:

- `-output-prefix log`
- `-output-prefix ./log`
- `-output-prefix /home/imitator/outputs`
-**output-result** *(default: false)* Writes the result of the analysis to a file named `<input_file>.result` using a normalized syntax, that can be easily parsed, e.g., using an external script.

-**output-states** *(default: false)* Generates a file `<input_file>.states` describing the reachable states in plain text (value of the location, of the discrete variables, associated constraint, and its projection onto the parameters).

-**output-tiles-files** *(default: false)* In cartography, generates the required files for each tile (works together with `-output-cart` and/or `-output-result`).

-**output-trace-set** *(default: false)* Graphical output using dot. In this case, IMITATOR outputs a file `<input_file>.pdf`, which is a graphical output in the PDF format, generated using dot, corresponding to the trace set.

Note that the path and the name of those two files can be changed using the `-log-prefix` option.

-**output-trace-set-nodetails** *(default: false)* In the graphical output of the trace set (see option `-output-trace-set`), does not provide detailed information on the local locations of the composed IPTA, and instead only outputs the state id. Enabling this option instead of `-output-trace-set` may yield a smaller graph, which is useful when generating large trace sets.

-**output-trace-set-verbose** *(default: false)* In the graphical output of the trace set (see option `-output-trace-set`), provides very detailed information, by adding to the right of the local locations of the composed IPTA the associated constraint as well. In addition, the parametric constraint is printed too. Enabling this option instead of `-output-trace-set` will yield a very large graph, and it is useful (and readable) mostly for very small trace sets.

-**PRP** *(default: false)* Deprecated option. Option used to activate the former and deprecated versions of PRP or PRPC [And+15]. These options must be used in addition to the `-mode` option. That is, in order to call the former version of PRP, use:

```
$ ./imitator model.imi model.pi0 -PRP
```

And in order to call the former version of PRPC, use:

```
$ ./imitator model.imi model.v0 -mode cover -PRP
```

Since version 2.9, it is advised to use instead `-mode PRP` and `-mode PRPC`, which call newly implemented versions of these algorithms, with a better structured result.

-**PTA2HyTech** *(default: false)* Translates the input model to a HyTech model, and exits. See Section 6.4 for details.

-**PTA2IMI** *(default: false)* Regenerates the model into an IMITATOR model, and exits.
-**PTA2JPG** *(default: false)*  Translates the input model to a graphical, human-readable form (in .jpg format), and exits.

-**PTA2PDF** *(default: false)*  Translates the input model to a graphical, human-readable form (in .pdf format), and exits.

-**PTA2PNG** *(default: false)*  Translates the input model to a graphical, human-readable form (in .png format), and exits.

-**PTA2TikZ** *(default: false)*  Translates the input model to a \LaTeX\ representation of the model (using the tikz package) without performing any analysis, and exits. Note that node positioning is not (much) supported, so may want to edit manually some positions.

-**PTA2Uppaal** *(default: false)*  Translates the input model to a UPPAAL model, and exits. See Section 6.3 for details.

-**romeo** *(default: false)*  April 1st, 2017 feature :-) Supposedly calls the Romeo model checker [Lim+09] instead of IMITATOR. Just try!

-**states-limit** *(default: none)*  Will try to stop after reaching this number of states. Warning: the program may have to first finish computing the current iteration (i.e., the exploration of the state space at the current depth) before stopping.

-**statistics** *(default: false)*  Print info on number of calls to PPL, and other statistics about memory and time. Warning: enabling this option may slightly slow down the analysis, and will certainly induce some extra computational time at the end.

-**step** *(default: 1)*  Step for the behavioral cartography. Integers can be used, or rationals (in the form $x/y$).

-**sync-auto-detect** *(default: false)*  IMITATOR considers that all the IPTA declaring a given action must be able to synchronize all together, so that the synchronization can happen. By default, IMITATOR considers that the actions declared in an IPTA are those declared in the synclabs section. Therefore, if an action is declared but never used in (at least) one IPTA, this label will never be synchronized in the execution\(^1\).

  The option **sync-auto-detect** allows to detect automatically the actions in each IPTA: the actions declared in the synclabs section are ignored, and IMITATOR considers as declared actions only the actions really used in this IPTA.

\(^1\)In such a case, action label is actually completely removed before the execution, in order to optimize the execution, and the user is warned of this removal.
-**time-limit** <limit> (default: none)  Try to limit the execution time (the value <limit> is given in seconds). Note that, in the current version of IMITATOR, the test of time limit is performed at the end of an iteration only (i.e., at the end of the exploration of the state space at the current depth). In the cartography mode, this option represents a **global** time limit, not a limit for each call to the inverse method.

-**timed** (default: false)  Add a timing information to each shell output of the program.

-**tree** (default: false)  Does not test if a new state was already encountered. To be set only if the reachability graph is a tree with all states being different (otherwise analysis may loop).

-**verbose** (default: standard)  Give some debugging information, that may also be useful to have more details on the way IMITATOR works. The admissible values for -**verbose** are given below:

- **mute**  No output (the result can be output to a file using -**output-result**)
- **warnings**  Prints only warnings
- **standard**  Give little information (number of steps, computation time)
- **experiments**  Give some additional information, typically enough for experiments
- **low**  Give some additional information on what happens internally
- **medium**  Give quite a lot of information
- **high**  Give much information
- **total**  Give really too much information

-**version**  Prints IMITATOR header including the version number and exits.
Chapter 9

Grammar

We give in this chapter the complete grammar of input models for IMITATOR.

9.1 Variable names

A variable name (represented by <name> in the grammar below) is a string starting with a letter (small or capital), and followed by a set of letters, digits and underscores ("_"). By letter we mean the 26 letters of the Latin alphabet, without any diacritic mark.

The set of clock names, parameter names and discrete variable names must (quite naturally) be disjoint. However, the sets of IPTA names, location names, action names, and variable names are not required to be disjoint. That is, the same name can be given to a clock, an automaton, an action and a location.

Furthermore, the names of the sets of locations of various IPTA are not-necessarily disjoint either: that is, a same name can be given to two different locations in two different IPTA (and they still represent two different things).

9.2 Grammar of the input file

The IMITATOR input model is described by the following grammar. Non-terminals appear within angled parentheses. A non-terminal followed by two colons is defined by the list of immediately following non-blank lines, each of which represents a legal expansion. Input characters of terminals appear in typewriter font. The meta symbol \( \epsilon \) denotes the empty string.

The text in green is not taken into account by IMITATOR, but allows some backward-compatibility with HyTech files [HHW95].

\[
\text{(imitator_input)} ::=
\text{(automata_descriptions)} \text{ (init)}
\]

We define each of those two components below.
9.2.1 Automata descriptions

\[
\langle \text{include\_file\_list} \rangle ::
\langle \text{include\_file} \rangle \langle \text{include\_file\_list} \rangle \\
| \epsilon
\]

\[
\langle \text{include\_file} \rangle ::
\#\text{include} "<\text{path}>" ;
\]

\[
\langle \text{automata\_descriptions} \rangle ::
\langle \text{include\_file\_list} \rangle \langle \text{declarations} \rangle \langle \text{automata} \rangle
\]

\[
\langle \text{declarations} \rangle ::
\text{var} \langle \text{var\_lists} \rangle \\
| \epsilon
\]

\[
\langle \text{var\_lists} \rangle ::
\langle \text{var\_list} \rangle : \langle \text{var\_type} \rangle ; \langle \text{var\_lists} \rangle \\
| \epsilon
\]

\[
\langle \text{var\_list} \rangle ::
\langle \text{name} \rangle \\
| \langle \text{name} \rangle = \langle \text{rational} \rangle \\
| \langle \text{name} \rangle , \langle \text{var\_list} \rangle \\
| \langle \text{name} \rangle = \langle \text{rational} \rangle , \langle \text{var\_list} \rangle
\]

\[
\langle \text{var\_type} \rangle ::
clock \\
| \text{discrete} \\
| \text{parameter}
\]

\[
\langle \text{automata} \rangle ::
\langle \text{automaton} \rangle \langle \text{automata} \rangle \\
| \langle \text{include\_file} \rangle \langle \text{automata} \rangle \\
| \epsilon
\]

\[
\langle \text{automaton} \rangle ::
\text{automaton} \langle \text{name} \rangle \langle \text{prolog} \rangle \langle \text{locations} \rangle \text{end}
\]

\[
\langle \text{prolog} \rangle ::
\langle \text{initialization} \rangle \langle \text{sync\_labels} \rangle \\
| \langle \text{sync\_labels} \rangle \langle \text{initialization} \rangle \\
| \langle \text{sync\_labels} \rangle \\
| \langle \text{initialization} \rangle \\
| \epsilon
\]

\[
\langle \text{initialization} \rangle ::
\text{initially} \langle \text{name} \rangle \langle \text{state\_initialization} \rangle ;
\]

### 9.3 Grammar of the reference valuation file

The reference valuation file (usually named `model.pi0`) gives a constant value to any parameter of the model; this file is used for IM and PRP.
It basically consists of a sequence of equalities \texttt{parameter = constant} separated (or not!) by the \& symbol. All parameters of the model must be given a valuation in this file; but the file may also use names that do not appear in the model (a warning will just be issued).

Arithmetic expressions (using integers and rationals) can even be used instead of just constants.

9.4 Grammar of the reference hyperrectangle file

The hyperrectangle file (usually named \texttt{model.v0}) defines a bounded parameter domain, \textit{i.e.,} a hyperrectangle having as dimensions the parameters of the model; this file is used for BC and PRPC.

It basically consists of a sequence of either equalities \texttt{parameter = constant} or intervals \texttt{parameter = constant .. constant} separated (or not!) by the \& symbol. All parameters of the model must be given an interval (possibly punctual) in this file; again, the file may also use names that do not appear in the model (a warning will just be issued).

Again, arithmetic expressions (using integers and rationals) can even be used instead of just constants.

9.5 Reserved words

The following words are reserved keywords and cannot be used as names for automata, variables, actions or locations.

\texttt{#include, accepting, always, and, automatically_generated.Observer, automatically_generated_x_obs, automaton, bad, before, carto, clock, constant, discrete, do, else, end, eventually, everytime, False, goto, happened, has, if, in, init, initially, invariant, loc, locations, maximize, minimize, next, not, once, or, parameter, projectresult, property, region, sequence, special_0_clock, stop, sync, synclabs, then, True, unreachable, urgent, var, wait, when, while, within}
Chapter 10

Missing features

Although we try to make IMITATOR as complete as possible, it misses some features, not implemented due to lack of time (contributors are welcome!) or due to complexity, or to keep the tool consistent. We enumerate in the following what seems to us to be the “most missing” features and, when applicable, we give hints to overcome these limitations.

10.1 ASAP transitions

ASAP (as soon as possible) transitions are transitions that can be taken as soon as all IPTA synchronizing with this transition can execute their local transition. This is different from urgent transitions, that must be taken in 0 time. Here, time can elapse, but not after all IPTA are ready to execute their local transition.

This is not supported by IMITATOR.

10.2 Parameterized models

Parameterized models are understood here as models with an arbitrary number of components (e.g., Fischer’s mutual exclusion protocol with $n$ processes), that would be instantiated (e.g., $n = 15$) before performing the analysis. IMITATOR does not currently support such parameterized models, and one should use copy/paste utilities to instantiate $n$ models. For complicated models with many processes, we usually write short scripts to generate the model (a script CSMACDgenerator.py to model the varying part of parameterized models for the CSMA/CD case study is available on the IMITATOR project on GitHub).

10.3 Other synchronization models

One-to-one synchronization could possibly be simulated by using as many transitions as pairs of IPTA in the model, although this may make the model rather complex.

Broadcast synchronization (“only the IPTA ready to execute a given transition execute it”) is not supported. Once more, it could possibly be simulated by using as many transitions as subsets of IPTA in the model, although this will make the model definitely complex.
Message passing is not supported. This can be easily simulated using dedicated discrete variables, that would be read / written in the transition.

10.4 Initial intervals for discrete variables

Discrete variables must be set to a constant rational in the \texttt{init} definition (e.g., \texttt{i = 0}). Setting a variable to an arbitrarily value (e.g., \texttt{i in [0 .. 10]}) is currently not supported. This can be simulated using an initialization IPTA that nondeterministically sets \texttt{i} to any of the values, in 0 time so as to not disturb the model.

10.5 Complex updates for discrete variables

So far, discrete variables can only be set to arithmetic expressions in $\mathcal{A}(D)$; hence, assigning a discrete variable to a clock, or to a parameter, or to any more complex expression, is not allowed. A reason for this restriction is that the value of the discrete variables would not anymore be constant (recall that discrete variables are syntactic sugar for locations).

However, this can be (partially) simulated with stopwatches: we can replace a discrete variable with a clock that is stopped in all locations (i.e., it does not evolve with time), and that is updated to the desired value (recall from Definition 3.1 that the clock updates allow assignments to linear expressions over clocks, discrete variables and parameters). However, in this latter case, the non-linear power of arithmetic expressions (multiplications and divisions between variables) cannot be used anymore.

10.6 Synthesis for L/U-PTA

\textsc{IMITATOR} does not implement specific algorithms for lower-bound / upper-bound PTA (L/U-PTA). This subclass of PTA, introduced in \cite{Hun+02}, constrains parameters to appear either always as upper-bounds in inequalities comparing them with clocks, or always as lower-bounds. L/U-PTA benefit from some decidability results (see e.g., \cite{Hun+02; BL09; JLR15; AM15; AL17}); however, exact synthesis seems to be intractable in practice \cite{JLR15; ALR16}. Still, some subclasses for which exact synthesis can be performed were proposed \cite{BL09; ALR18a}.

However, \textsc{IMITATOR} does detect whether an input model is an L/U-PTA, in which case a message is printed with the list of lower-bounds parameters and upper-bounds parameters.

\begin{remark}
Note that our definition of L/U-PTAs is consistent with that of, e.g., \cite{BL09}; however, we do not consider the constraint of the initial state while checking for the L/U nature of the model. That is, we refer to as L/U-PTAs even for the constrained L/U-PTAs of \cite{BL09}.
\end{remark}
Chapter 11

Acknowledgments

Étienne André initiated the development of IMITATOR in 2008, and keeps developing it. Emmanuelle Encrenaz and Laurent Fribourg have been great supporters of IMITATOR, on a theoretical point of view, and to find applications both from the literature and real case studies. Abdelrezzak Bara provided several examples from the hardware literature. Jeremy Sproston provided examples from the probabilistic community. Bertrand Jeannet has been of great help on the linking with Apron [JM09] in a previous version of IMITATOR. Ulrich Kühne made several important improvements to IMITATOR, and linked the tool to PPL. Daphne Dussaud implemented the graphical output of the behavioral cartography. Romain Soulat implemented in part the merging technique [AFS13], and brought several case studies. Giuseppe Lipari and Sun Youcheng provided examples from the real-time systems community, and collaborated on several algorithms. Camille Coti, Sami Evangelista and Nguyên Hoàng Gia worked on the distributed version of IMITATOR. Nguyễn Hoàng Gia worked on the non-Zeno synthesis algorithms. Laure Petrucci implemented an NDFS algorithm. Stéphane Rosse improved a script for comparing results and speeds of various versions of IMITATOR. Vincent Bloemen implemented the optimal-time reachability synthesis. Jaime Arias simplified a lot the source code management and implemented new features. Jiří Srba suggested the translation of IMITATOR’s strong broadcast into UPPAAL.

We acknowledge the help of the PPL [BHZ08] developers for their help with solving several issues over the years, and more generally for making this very useful library available.
